CLOUD COMPUTING TECHNOLOGY – CLIENTS & SECURITY (SIMPLE EXPLANATION)

CLOUD CLIENTS

Meaning of Clients

Clients are the devices used by end users to access cloud data and applications.

- They are the interface between users and the cloud.
- Different types of clients exist
- Each client provides a different way to interact with cloud services
- Organizations may use one or more client types depending on their needs

Interaction depends on:

- User requirements
- Benefits and limitations of each client type

MOBILE CLIENTS

Meaning

Mobile clients include:

- Laptops

- PDAs
- Smartphones (e.g., iPhone, BlackBerry)

Characteristics of Mobile Clients

- Smartphones and PDAs usually cannot run heavy or robust applications
- Laptops, however, can:
  - Connect to the cloud
  - Access applications just like a desktop computer

Limitations of Mobile Clients

- Security concerns
- Speed issues, because:
  - Users connect from different locations (hotels, public Wi-Fi)
  - Network connections may not be optimized

👉 Therefore, mobile users usually do not upload large amounts of data.

Mobile Application Development

Cloud applications can be designed specifically for mobile users

Even though mobile users don't input large data:

- They can still access cloud databases and applications

Security: Two-Sided Issue

Risk 1: Laptops and mobiles are easy to lose or steal → data can be compromised

Benefit:

- If data is stored in the cloud and only limited files are on the device
- Loss of device compromises only minimal data

TYPES OF CLOUD CLIENTS

THIN CLIENTS

Meaning

Thin clients are computers that:

- Have no hard drive
- Have no DVD-ROM
- Only display what is on the server

Usage of Thin Clients

Useful mainly when:

- Organization has an in-house cloud
- Users access cloud-based services
- Users access a virtualized server

Advantages of Thin Clients

- ✓ Less expensive than thick clients
- ✓ Low maintenance cost
- ✓ Use less energy
- ✓ High security, because:
  - No data is stored on the client
  - All data stays in the data center or cloud
  - Lower risk of physical data breach

THICK CLIENTS

Meaning

Thick clients are traditional computers that:

- Have local storage
- Run applications installed on the machine

Characteristics

- Already used in most organizations
- Some applications can be moved to the cloud
- Mission-critical applications may need to stay in-house

Advantages of Thick Clients

- ✓ Can connect to virtualized servers
- ✓ No need to buy new hardware
- ✓ Useful when:
  - Users must store files locally
  - Applications are not available in the cloud

Disadvantages (Security & Reliability)

- ❌ More vulnerable to attacks
- ❌ Data stored on hard drive can be compromised if stolen
- ❌ Reliability issues:
  - Thin client failure → plug in another device, work continues
  - Thick client failure → OS, data, and settings are lost and must be reconfigured

SECURITY IN CLOUD COMPUTING

Importance

Security is the number one concern in cloud computing because:

- Data is stored by a third party
- Organizations don't have full visibility into internal operations

However, cloud computing also provides strong security benefits.

DATA LEAKAGE

Issue: Data stored in many places (laptops, desktops) increases risk

Thick clients often store: Downloaded files, Unencrypted data

Cloud Advantage: Centralization of data, Thin clients reduce local storage, Lower chance of data leakage

OFFLOADING WORK (SECURITY RESPONSIBILITY)

Meaning: Security responsibility is offloaded to the cloud provider

Providers often offer better security than in-house systems

Why Cloud Providers Are Stronger:

- Economies of scale: Many paying customers, More money for stronger security
- Providers want a good reputation
- Result: More advanced security features

LOGGING

Meaning: Logging records system activity for monitoring and investigation.

Cloud Advantage:

- Cloud providers can: Add large amounts of memory, Maintain detailed and extended logs
- Better than in-house environments where logging is often limited

FORENSICS

Meaning: Forensics refers to investigating security breaches.

Cloud Benefits:

- ✓ Faster response with minimal downtime
- ✓ Forensic servers can be created on demand
- ✓ Virtual machines can be cloned for offline analysis
- ✓ Many companies lack in-house incident response teams

Without cloud: IT staff must shut down servers, Investigate quickly, Restore service with minimal downtime (very difficult)

SECURITY DEVELOPMENT

Security vendors are actively: Developing products for virtual machines, Creating tools specifically for the cloud. Cloud offers new opportunities for innovative security solutions.

AUDITING

Meaning: Auditing ensures systems meet security and regulatory requirements.

Challenge: Cloud data is stored on someone else's equipment. Adds complexity compared to securing a local network.

COMPLIANCE

Meaning: Compliance means following laws and industry regulations.

Examples of Regulations:

- SOX (Sarbanes-Oxley)

- GLBA (Gramm-Leach-Bliley Act)
- HIPAA
- PCI DSS (Payment Card Industry Data Security Standard)

Compliance Before SaaS: Organizations had to: Identify users and access privileges, Identify sensitive data, Identify where data is stored, Identify encryption methods, Document everything for auditors.

Compliance Challenges with SaaS: Data location is not always known. Data may be stored: On provider's equipment, On partner infrastructure. Makes compliance more complicated.

WEB APPLICATION BREACHES

Meaning: Web application breaches occur when attackers exploit weaknesses in cloud-based web applications.

Important Points:

- Cloud service providers use many web connections, so web application security is critical.
- Providers should follow OWASP (Open Web Application Security Project) guidelines for secure application development.
- This is similar to PCI Requirement 6.5, which requires secure coding practices based on OWASP standards.

What Organizations Should Ask Providers

- How do they handle security breaches internally?
- How do they train staff to prevent breaches?
- Where is data stored geographically?

Data Location Concern

- Cloud servers can be located anywhere in the world
- Example: Brazil, Germany, Thailand
- This raises concerns about data privacy, laws, and compliance

VPNS IN CLOUD COMPUTING

Telecommuting and Cloud

Meaning: Cloud applications allow employees to work remotely (telecommute).

Organizations can reduce: Office space, Utility costs, On-site infrastructure.

Reality Check: Not all jobs support telecommuting. Some applications and services still need to stay in-house (file storage, email, productivity tools).

Need for Secure Remote Access

Whether employees access cloud services:

- From home
- From office
- Over public Internet

👉 A secure remote access solution is required.

SSL VPN

What is an SSL VPN?

An SSL VPN (Secure Sockets Layer Virtual Private Network):

- Allows secure access using a standard web browser
- Does not require special client software

SSL VPN vs IPsec VPN

SSL VPN	IPsec VPN
Uses web browser	Requires client software
Less management overhead	More complex
Easier for end users	Harder to manage

SSL Technology

- SSL secures message transmission over the Internet
- Built into browsers and web servers
- Uses public-key and private-key encryption (RSA)

Advantages of SSL VPN in Cloud

- ✓ Secure data transmission
- ✓ Less PKI overhead than IPsec VPN
- ✓ On-demand client support
- ✓ Easy to use and manage

Endpoint Security Checks

SSL VPN ensures users follow security policies by:

- Requiring antivirus software
- Verifying OS patches
- Checking for malware or bots

Overall Benefit

Simple, Cost-effective, Secure, Enables more telecommuting.

KEY MANAGEMENT IN CLOUD COMPUTING

Why Key Management Is Important

- Data is stored off-site and not under direct control
- Cloud vendors try to secure data, but risk still exists

Risks Involved

- Accidental data exposure
- Data not fully erased when deleted
- Cloud providers may: Not wipe free storage, Not destroy data on failed hardware

Man-in-the-Middle Attacks

- Attackers may intercept communication
- Safeguards must be in place

Cryptographic Protection

- **Authentication:** Use client and server certificates. Confirms you are connecting to the correct cloud service.
- **Authorization:** Use systems like Kerberos. Ensures proper authentication and access control.
- **Data Encryption:** Cloud data must be encrypted. Data should be destroyed when the encryption key is destroyed.

Types of Keys Used

- Transport keys
- Authentication keys
- Authorization tokens
- File encryption keys
- Hardware storage keys
- Revocation keys

- Certificates

👉 More security = more keys to manage

CLOUD CONNECTIVITY OPTIONS

BASIC PUBLIC INTERNET

Meaning: Uses regular Internet connection (ISP, broadband, dial-up). Most common and simplest cloud access method.

Characteristics: No TCP acceleration, No compression, No application-specific optimization.

Advantages: ✓ Large audience, ✓ Highly fault tolerant, ✓ Multiple ISPs available, ✓ Encrypted access using SSL / HTTPS, ✓ Cost-effective

Disadvantages: ❌ No end-to-end QoS, ❌ Difficult to guarantee SLAs, ❌ Poor performance over high-latency networks, ❌ TCP, HTTP inefficiencies, ❌ Downtime beyond your control

THE ACCELERATED INTERNET

Meaning: Uses advanced application delivery features on top of Internet connectivity.

Benefits:

- ✓ 20%–50% cloud performance improvement
- ✓ Offloads network tasks from servers
- ✓ SSL termination
- ✓ TCP connection management
- ✓ Dynamic caching
- ✓ Compression and prefetching
- ✓ Over 50% performance improvement for users

Providers Offering Acceleration: AT&T Hosting, Citrix NetScaler, F5 WebAccelerator

Key Considerations: Focus on: SLAs, Monthly bandwidth charges. Not on how acceleration is implemented.

Requirements: Server-side appliance at the cloud, Downloadable client at end-user side.

CLOUD COMPUTING TECHNOLOGY

Optimized Internet Overlay, Connectivity, Redundancy & Cloud Services (Simple Explanation)

OPTIMIZED INTERNET OVERLAY

Meaning: An Optimized Internet Overlay allows customers to access the cloud using the public Internet, but performance is improved at the cloud provider's network, especially at Points of Presence (POP).

Enhancements at POP (Points of Presence)

- **Optimized Real-Time Routing:** Traffic is routed through faster paths, Avoids network slowdowns, Makes it easier to meet SLAs (Service Level Agreements)
- **SSL Session Termination:** SSL session is stopped at the POP, Data and protocols are optimized, Traffic is then re-encrypted before sending
- **Application Logic at POP:** Part of the application runs at the POP, Improves: Scalability, Fault tolerance, Response time (often over 80% improvement)
- **Local Caching:** Frequently accessed content is delivered from local caches, Reduces latency and improves speed

Disadvantages of Optimized Internet Overlay

- ❌ More expensive than basic Internet access (up to 4 times costlier)
- ❌ Vendor lock-in, since application logic is distributed into the provider's network

SITE-TO-SITE VPN

Meaning: A Site-to-Site VPN connects an organization directly to the cloud provider using a private WAN, usually through MPLS/VPN.

Advantages:

- ✓ Confidentiality
- ✓ Guaranteed bandwidth
- ✓ SLAs for: Availability, Latency, Packet loss
- ✓ MPLS can scale with changing bandwidth needs
- ✓ QoS (Quality of Service) can be included in SLAs

Disadvantages:

- ❌ Private WANs are not always more reliable than Internet connections
- ❌ Often less reliable than using multiple redundant ISP connections
- ❌ Higher cost

CLOUD PROVIDERS – NETWORK CONNECTIVITY

Key Needs

Cloud providers use distributed services, Require robust connectivity.

Private Tunnels: Ensure stable: Bandwidth, Latency, Packet loss. Provide: Encryption, Strong authentication.

Cost Challenge

Growing cloud providers face high bandwidth costs. Traffic includes: Client-to-cloud traffic, Inter-provider traffic.

Large Provider Advantage

Companies like Google build their own private WANs. Use multiple peering points with major ISPs. Helps reduce bandwidth charges.

CLOUD CONSUMERS

Large Organizations

Build distributed IT infrastructure. Connect data centers using private fiber optic networks. Depends on: Distance, Bandwidth needs, Budget.

Access Methods

- Major sites → Corporate WAN
- Smaller offices & mobile users → VPNs over optimized and accelerated Internet

VPN Usage Rule: VPN over Internet is best as primary link only when high performance is not critical.

PIPE SIZE (BANDWIDTH)

Meaning: Bandwidth is the speed or throughput of your Internet connection.

Factors Beyond Your Control: Internet bandwidth between your organization and the cloud, Round-trip time (latency), Cloud response time.

UPSTREAM / DOWNSTREAM

- **Symmetric Connection:** Same speed for sending and receiving data

- **Asymmetric Connection:** Upload speed < Download speed. Example: ADSL ("A" = Asymmetric). Example speeds: Download: 1.5 Mbps, Upload: 750 Kbps.

Business Connections

Most organizations use symmetrical connections. More robust than DSL.

Internet Reality

Internet traffic routes change constantly. Speed fluctuates. Achieving 85% of nominal bandwidth consistently is considered good performance.

Best Practice

Test Internet speed multiple times a day. Especially: Early morning, Peak hours.

HOW MUCH BANDWIDTH DO WE NEED?

Key Questions: How much data moves in and out of the cloud? How many users access cloud services?

Important Points: Most organizations already have sufficient bandwidth. Cloud usage increases bandwidth demand. Insufficient capacity causes slowdowns for everyone.

Recommendation

- ✓ Calculate capacity needs
- ✓ Ensure enough bandwidth
- ✓ Secure an SLA that meets requirements
- ✓ SLAs provide: Guaranteed performance, Remediation if ISP fails

REDUNDANCY

Meaning: Redundancy ensures reliability and uptime by avoiding single points of failure.

- **Traditional Redundancy:** Extra servers added to data centers
- **Redundancy with Virtualization:** Virtual servers cloned on same or different physical machines, Entire VMs replicated for failover
- **Redundancy in the Cloud:** More complex and distributed. Data may be: Stored in multiple locations, Spread across the country.

How Cloud Providers Handle Redundancy

They don't add new physical servers for you. They reallocate resources dynamically. Redundancy is handled transparently.

CLOUD SERVICES

Different services affect how cloud infrastructure is designed.

IDENTITY SERVICES

Meaning: Applications need a digital identity to: Identify users, Decide access rights.

In-House Identity: Uses Active Directory

Cloud Identity: Cloud providers use their own identity systems: Amazon → Amazon identity, Google App Engine → Google account, Microsoft → Windows Live ID.

OpenID

Meaning: OpenID is an open, decentralized single sign-on standard.

Features: Identity is a URL, No central authority, Supports: Passwords, Smart cards, Biometrics.

Organizations Using OpenID: Google, IBM, Microsoft, Yahoo.

INTEGRATION

Meaning: Integration allows applications to communicate with each other.

On-Premises Integration: Message queues, Integration servers.

Cloud Integration

- **Amazon SQS (Simple Queue Service):** Message-based communication in the cloud, Messages are replicated, No guaranteed order of delivery, High scalability.
- **BizTalk Services:** Uses relay services instead of queues, Helps applications communicate through firewalls.

Key Challenge: Cloud integration often crosses organizational boundaries. Firewall tunneling is critical.

MAPPING SERVICES

Meaning: Mapping is provided as a cloud service.

Example: Websites show: Hotel locations, Restaurant directions.

Cloud Advantage: Developers don't need their own mapping database. Services like: Google Maps, Microsoft Virtual Earth. Can be easily embedded in websites.

PAYMENTS

Meaning: Cloud-based payment services allow organizations to accept online payments.

Options: Credit card processing services, PayPal.

Benefit: Easy online payments, No need to build payment systems from scratch.

SEARCH SERVICES

Meaning: Search services allow applications to embed search functionality.

Example: Microsoft Live Search. Can search: Organization's database, Entire Internet.

Example Scenario: Movie database application: Searches internal movie records, Also searches the web, Returns combined results.

BASIC REQUIREMENTS

To access cloud services: ✓ A computer, ✓ An Internet connection

WEB APPLICATION FRAMEWORK (SIMPLE EXPLANATION)

A web application framework helps developers build:

- Dynamic websites
- Web applications
- Web services

Purpose of a Framework

- Reduces development overhead
- Avoids rewriting common code again and again
- Provides pre-written libraries

👉 Developers don't need to "reinvent the wheel" every time.

Evolution of Web Applications

- **Early Web:** Websites were written using HTML (Hypertext Markup Language), Pages were static, Any change had to be done manually by the author.

- **Dynamic Web – CGI:** As the web evolved, CGI (Common Gateway Interface) was introduced, Allowed external applications to interact with web servers, Enabled dynamic content generation.

ACCESSING THE CLOUD – AJAX

What is AJAX?

AJAX (Asynchronous JavaScript and XML) is a set of web development techniques used to create interactive web applications.

Key Feature of AJAX

- Data is retrieved from the server asynchronously
- Happens in the background
- Does not reload or disturb the current page

👉 This makes web applications more responsive.

AJAX Technologies

AJAX is not a single technology. It includes:

- XHTML & CSS – Presentation
- DOM (Document Object Model) – Dynamic interaction with data
- XML & XSLT – Data interchange and manipulation
- XMLHttpRequest – Asynchronous server communication
- JavaScript – Ties everything together

Alternatives to XML

Advantages of AJAX

- ✓ Avoids duplicate content across pages
- ✓ Retrieves only new data instead of reloading pages
- ✓ Reduces bandwidth usage
- ✓ Faster load times
- ✓ More interactive user experience
- ✓ Scripts and stylesheets are downloaded only once
- ✓ Fewer server connections

Disadvantages of AJAX

- ❌ Pages don't appear in browser history
- ❌ Back button may not work properly

APIS (APPLICATION PROGRAMMING INTERFACES)

What is an API?

An API is a set of rules that lets programs communicate with other programs.

- APIs are not user interfaces
- Used behind the scenes
- Allow software reuse

> **Example:**
>
> Amazon API allows third-party sites to access Amazon products. Credit card verification uses APIs without user awareness.

Benefit

Developers don't start from scratch. Applications can delegate tasks like: Email, Billing, Payments.

HOW APIs WORK (Simple Explanation)

An API (Application Programming Interface) is a set of rules that defines how two software applications communicate with each other.

👉 APIs allow applications to talk to each other automatically, without user involvement.

APIs and Web Services

APIs usually work using web services. Web services use standards so different systems can communicate over the Internet.

Role of XML in APIs

What is XML? XML (Extensible Markup Language) is a general-purpose markup language. It stores data in a structured format. Both humans and computers can read and write XML.

API Communication

APIs are written as a series of XML messages. These messages are sent and received over the Internet.

> **Example: Google Maps API**
>
> A website can use Google Maps by including code like:
>
> - A script that loads Google Maps
> - A function that: Creates a map, Sets a location (latitude & longitude), Displays the map on the webpage
>
> 📌 **Real-life example:** A hotel website shows its location using Google Maps without creating its own mapping system.

How Programmers Use APIs

Programmers write applications that generate the correct XML messages. These messages are sent to remote cloud applications.

> 📌 **Example:**
>
> To archive emails in the cloud: An API automatically sends emails from inboxes, Emails are stored in cloud storage, No manual work required.

SDK (Software Development Kit)

Companies often release APIs as part of an SDK. An SDK includes: API, Programming tools, Documentation. 👉 This makes development easier and faster.

APIs Are Invisible to Users

Users never see APIs working. APIs run silently in the background. They only do the job they were created for.

> 📌 **Example:**

> When you pay online: You only enter card details, APIs send data to payment servers, Verification happens automatically.

Standards Used by APIs

- **SOAP (Simple Object Access Protocol):** Uses XML to encode messages. Works across: Any operating system, Any network protocol.
- **UDDI (Universal Description, Discovery, and Integration):** An XML-based directory. Helps businesses: List services, Discover other services, Collaborate using web services.
- **WSDL (Web Services Description Language):** XML-based language. Describes what a web service does. Used within UDDI. Often called the "SOAP of UDDI".

API CREATORS

Organizations can: Use existing APIs, Create their own APIs. APIs help link cloud applications with organizations.

GOOGLE GADGETS API

What are Google Gadgets?

Gadgets are small applications used with Google Desktop Search. Help users search: Emails, Files, Web history, Chats.

Languages Used in Google Gadgets API

1. XML

- Used to write gadget specifications
- A gadget is simply an XML file
- XML tells Google: How to process the gadget, How to display it

2. HTML

- Formats web pages
- Used for static content

👉 **Difference:** HTML → formats web pages, XML → describes structured data.

3. JavaScript

- Adds dynamic behavior
- Makes gadgets interactive

Google Desktop Search Features

- ✓ System-wide search (email, documents, chats, history)
- ✓ Very high search speed
- ✓ Searches computer and web together

CLOUD STORAGE

What is Cloud Storage?

Cloud storage means storing data on remote servers connected to the Internet, instead of storing it only on your own computer or local hard drive.

Key Advantages of Cloud Storage

- Data can be accessed from any location with Internet access
- Users do not need the same computer every time
- No need to carry physical storage devices (USB, hard disk)

> 📌 **Example:**
>
> You upload files to Google Drive and can open them from your phone, laptop, or office computer.

Types of Cloud Storage Systems

There are hundreds of cloud storage providers. Some are specialized: Email storage (Gmail), Photo storage (Flickr, Picasa). Others store any type of data. Providers range from small

companies to huge data centers.

How a Cloud Storage System Works

- A cloud storage system needs a data server connected to the Internet
- The user (subscriber) uploads files to the server
- The server records and stores the data
- When needed, the user: Logs in through a web-based interface, Downloads files or Accesses and edits data directly online

> 📌 **Example:**
>
> Editing a document directly in Google Docs without downloading it.

Redundancy in Cloud Storage

Cloud storage systems use dozens or hundreds of data servers. Data is stored on multiple machines (called redundancy). Ensures data availability even if: A server fails, A power supply fails. 👉 Without redundancy, providers cannot guarantee access at all times.

Why People Use Cloud Storage for Safety

Many users already have enough local storage. They use cloud storage for data protection.

> 📌 **Example:**
>
> If an office building is destroyed by fire or flood, cloud-stored data is still safe.

STORAGE AS A SERVICE (SaaS)

What is Storage as a Service?

- A third-party provider rents storage space
- Customers pay only for what they use

When SaaS is Useful

When companies: Lack budget for storage infrastructure, Lack technical staff to maintain storage. Popular with small and medium businesses.

Cost Benefits

No need to buy storage hardware. Pay based on: Cost per gigabyte stored, Cost per data transferred.

How Backup Works

Customer uses client software, Selects data to back up, Data is transferred over a WAN. If data loss occurs, data is retrieved from provider.

> 📌 **Example:**
>
> Restoring deleted files from an online backup service.

CLOUD STORAGE PROVIDERS

Examples of Providers

Google Docs – documents, spreadsheets, presentations. Gmail, Hotmail, Yahoo Mail – email storage. Flickr, Picasa – photo storage. YouTube – video storage. HostMonster, GoDaddy – website storage. Facebook, MySpace – social media content. MediaMax, Strongspace – general-purpose storage.

Pricing Models

Many services offer free storage. Paid plans charge: Per stored gigabyte, Based on data transfer. Competition has caused prices to drop. Some providers offer free limited storage.

SECURITY IN CLOUD STORAGE

- **Encryption:** Uses complex algorithms to encode data. Requires an encryption key to decode. Very difficult for hackers to crack.
- **Authentication:** Requires username and password.
- **Authorization:** Defines who can access what. Multiple access levels exist.

> 📌 **Example:**
>
> Employee → limited access, IT head → full access.

Security Concerns

Risk of hacking remote systems. Risk of insider threats (disgruntled employees). Credentials could be misused.

RELIABILITY IN CLOUD STORAGE

Why Reliability Matters

Unreliable storage becomes a liability. Users won't trust: Unstable systems, Financially unstable providers.

How Providers Handle Reliability

Use redundancy. Still, failures are possible. Reputation is critical: Unreliable providers lose customers, Many competitors exist in the market.

ADVANTAGES OF CLOUD STORAGE (Summary)

- ✓ Data stored across multiple data centers
- ✓ Load balancing improves performance
- ✓ Faster access by storing data closer to users
- ✓ Disaster protection
- ✓ Off-site backups improve business continuity

> 📌 **Example:**
>
> If a hurricane destroys local servers, cloud backups allow recovery.

Vendor Selection Considerations

Vendor choice can be complex. Storage interaction methods vary: Agent-based (automatic transfer via FTP), Web-based frontend (manual file upload). Amazon S3 is the most well-known cloud storage solution. Suitable for many use cases. Large enterprises may prefer vendors offering: Strong SLAs, Direct customer support.

CLOUD STORAGE – CAUTIONS

(Things to be careful about)

1. Mixed Approach is Better: Cloud storage is still immature. Do not move everything to the cloud at once. Use the cloud first for non-critical data.

> 📌 **Example:**
>
> Store backups or documents in the cloud, but keep core business databases locally.

2. Portability and Vendor Issues: Large enterprises may face problems with vendors like Google or Amazon. Applications may need to be rewritten. Lack of portability (hard to move from one provider to another).

> 📌 **Example:**
>
> An app built for Amazon S3 may not work directly on another provider.

3. Better Compatibility Vendors: Some vendors like 3tera support: LAMP, Solaris, Java, Windows .NET. 👉 This makes migration easier.

4. Price and Reliability – Deal Breakers: The biggest concerns are: Cost, Reliability. One mistake by the vendor can lead to irretrievable data loss.

5. Vet the Vendor Carefully: Check: SLA, Backup policy, Support quality. Many companies take an "appetizer approach": Test 1–2 services, Check compatibility with existing IT systems, Then decide whether to expand cloud usage.

LEGAL AND CONTRACT ISSUES

Legal restrictions apply to: Copyrighted music, Videos, Licensed data. Vendors offer different guarantees. You must know: What the vendor will do, What the vendor will not do if data is lost or compromised.

Best Practice

✓ Use multiple redundant systems, ✓ Local backup + offsite backup, ✓ Sync + archive.

CLOUD STORAGE OUTAGES

Example: Amazon S3 Outage (Feb 2008): Massive outage affected many applications. Clients could not access data. Amazon: Added capacity, Fixed authentication issues, Reported no data loss due to redundancy. 👉 Even if data is safe, access may be unavailable.

Lesson: Cloud outages can happen. Always plan for downtime. Use caution before fully depending on cloud storage.

DATA THEFT RISKS

Data stored outside your data center increases security risk. Risk of: Hackers, Unauthorized access, Insider misuse.

Multi-Tenant Risk: Providers store data of many customers together. Your data may sit next to a competitor's data.

Protection Measures: ✓ Encrypt stored data, ✓ Secure data in transit using SSL.

CLOUD STORAGE PROVIDERS

Hundreds of providers exist. New providers appear regularly. Major players include: Amazon, Nirvanix, Google (GDrive – planned), EMC, IBM BlueCloud.

BitTorrent support (S3 acts as seed). HTTP access logging. Logs stored in another bucket. Logs used for data mining.

Amazon's Vision: "Amazon S3 helps developers focus on innovation, not storage."

EARLY AMAZON S3 APPLICATION – REAL EXAMPLE

NASA Stardust@Home Project: Used by University of California, Berkeley. Stored 60 million images. Images distributed to 100,000 volunteers worldwide. S3 allowed: Rapid scaling, No infrastructure investment, Easy ramp-up and ramp-down.

NIRVANIX

Uses custom software and file systems. Runs on Intel storage servers. Data centers on both US coasts. Continues expanding to new locations.

SDN (Storage Delivery Network) – Nirvanix

What is Nirvanix SDN? SDN (Storage Delivery Network) by Nirvanix turns a normal 1U server into infinite-capacity Network Attached Storage (NAS). It integrates easily with an organization's existing backup and archive systems. Earlier, cloud storage was mainly used by application developers. Now, enterprises are using cloud storage as a low-cost storage tier for: Backup, Archiving, Long-term storage. 📌 As noted by Gartner analyst Adam Couture.

How Nirvanix SDN Works

Nirvanix built a global cluster of storage nodes called the Storage Delivery Network (SDN). It is powered by the Nirvanix Internet Media File System (IMFS). SDN: Stores data, Delivers data, Processes requests from the best network location, giving users the best performance.

Key Features of Nirvanix SDN

- ✓ Stores multiple copies of files
- ✓ Copies are stored in multiple geographic locations

- ✓ Provides very high data availability
- ✓ Improves user experience worldwide

Nirvanix Cloud NAS for Linux

Mounts cloud storage as a virtual drive. Can be accessed using: NFS, CIFS, FTP. After Installation: Storage admins can apply: File permissions, Directory permissions, Access permissions. Users access the cloud drive using existing applications.

Advanced SDN Capabilities

- ✓ Automated policy-based file replication
- ✓ Single global namespace (scales to petabytes)
- ✓ Secure, encrypted data storage
- ✓ Data stored across globally clustered storage nodes

Benefits of Cloud NAS (Cloud Network Attached Storage)

Cost & Efficiency: 80–90% cost savings over traditional storage. No large capital expenditure. 100% storage utilization.

Security & Recovery: Encrypted off-site storage. Integrated with existing backup systems. Built-in disaster recovery. Automatic replication to up to 3 geographic locations. Supports 100% SLA.

Speed: Data available in seconds. Much faster than tape backups (hours or days).

Who Should Use Cloud NAS?

Cloud NAS is ideal for: Long-term data archiving, Backup repositories, Unstructured data storage, Automated file transfer systems.

Example Use Cases: Disk-to-disk-to-cloud replacing tape backups, Department-wide backup of all computers, Centralized shared data repository.

Google Bigtable Datastore

What is Bigtable?

Bigtable is Google's highly scalable cloud database. Designed for: High speed, Flexibility, Massive scalability. Can store petabytes of data. Runs across thousands of distributed servers. Available via Google App Engine.

How Bigtable Works (Simple View)

Bigtable is a distributed DBMS. Data is stored across many commodity servers. Tables are: Multidimensional, Sparse maps (rows + columns). Each cell has a timestamp.

📌 **Why timestamps matter?** They allow: Multiple versions of data, Selecting older versions, Deleting data older than a certain time.

Tablets in Bigtable

Large tables are split into tablets. Each tablet ≈ 200 MB. One server stores ~100 tablets. Data is spread across many servers and locations.

Reliability & Performance

- ✓ Load balancing: busy tablets moved to other servers
- ✓ Machine failure → users may not notice
- ✓ Automatic compression to free disk space
- ✓ Three-tier lookup system: META0 → META1 → Tablet locations
- ✓ Uses caching and prefetching to avoid bottlenecks

Issues with Bigtable

- ❌ Proprietary system
- ❌ Vendor lock-in (locked into Google)
- ❌ Similar issue with Amazon AWS

Cost (Comparable to Amazon S3)

CPU: $0.10–$0.12 per core-hour. Storage: $0.15–$0.18 per GB-month. Outgoing bandwidth: $0.11–$0.13 per GB. Incoming bandwidth: $0.09–$0.11 per GB.

Final Note on Cloud Storage

"Cloud storage" is often used as a buzzword. If overused, it may mean any Internet-based storage. Organizations should view cloud computing as: Scalable IT capabilities delivered over the Web.

CLOUD APPLICATION

A cloud application is software that runs on the cloud, not on the user's computer. Users do not need to install the application locally. They access it through the Internet, usually using a web browser. Example: Gmail, Google Docs, Salesforce. To make this work, there must be a standard way for the client (browser) and cloud to communicate.

HTTP (Hypertext Transfer Protocol)

HTTP is the main protocol used to transfer data between your computer and the cloud. It is the basic "language" used by browsers and web servers.

Stateless Nature of HTTP

HTTP is stateless → it does not remember users between requests. This is good because servers don't need to store user details. But it creates a problem: 👉 How does a website remember who you are?

Solution: Cookies. Websites use cookies to: Track user login, Remember shopping carts, Maintain session state.

Simple HTTP Example

```
Browser Request:
GET / HTTP/1.0
Host: www.velte.com

Server Response:
HTTP/1.0 200 OK
Content-Type: text/html
<title>Thank you for visiting Velte Publishing</title>
```

Explanation:

- `GET / HTTP/1.0` → Browser wants the homepage using HTTP 1.0

- `Host:` → Tells which website is requested
- `200 OK` → Request was successful

HTTP 1.0 vs HTTP 1.1

- **HTTP 1.0:** Opens a new connection for: Page, Images, Scripts.
- **HTTP 1.1:** Keeps the connection open, Transfers all components together, Faster and more efficient.

HTTP Requests (Methods)

HTTP defines 8 request methods (like GET, POST, etc.). These tell the server what action to perform. Data can be: Pre-existing, Dynamically generated. HTTP is still the most common way browsers connect to the cloud.

XMPP (Extensible Messaging and Presence Protocol)

XMPP is being considered as a future protocol for cloud computing.

Unlike HTTP-based protocols: HTTP is one-way, XMPP is two-way.

Why is this important? HTTP requires polling. XMPP allows real-time communication.

The Problem with Polling

Polling means: Client keeps asking: "Any update? Any update?". Example: Email clients checking for new mail, Twitter servers getting overloaded.

> 📌 **Example:**
>
> Twitter once handled 200–800 requests per second. During Macworld keynote, Twitter crashed due to polling.

Why XMPP is Better

Eliminates polling. Supports real-time updates. XML-based and extensible. Scales to millions of users. Originally designed for instant messaging.

❌ **Limitation:** Not based on HTTP. Firewalls and web standards still favor HTTP.

Security in Cloud Communication

Cloud security relies on: Encryption, Authentication.

SSL (Secure Sockets Layer)

SSL creates an encrypted connection between browser and server. Ensures data privacy (passwords, credit cards).

How SSL Works (Steps)

1. Browser checks website's SSL certificate
2. Browser and server agree on encryption type
3. Exchange encryption keys
4. Encrypted communication starts
5. Lock icon appears in browser

📌 **Only visible effect:** Page loads slightly slower.

SSL Certificate Contains

Domain name, Company name, Address, Certificate authority, Expiry date. If any check fails → browser warns user.

OpenID

OpenID lets you use one login for multiple websites. You choose a trusted OpenID provider. You keep the same identity even if you change providers.

Benefits: No need for many usernames/passwords, Free and open source, Lower management cost. Used by companies like: AOL, Microsoft, Sun, Novell.

PCI DSS and Cloud Computing

PCI DSS = Payment Card Industry Data Security Standard.

Rule: "Only one primary function per server"

In Virtualized Environments: One physical server can host multiple virtual machines. Allowed if systems are isolated and segmented. 📌 PCI rules will evolve as cloud and virtualization grow.

How HTML Works

HTML uses tags written inside < >. Browser reads HTML and displays content visually.

> Example: `<b>This text is bold</b>`
> Tags don't appear on the page. They control how content looks.

CSS (Cascading Style Sheets)

CSS controls presentation: Colors, Layout, Fonts. Makes pages more attractive and accessible.

JavaScript

Adds interactivity. Enables: Form validation, Animations, Dynamic content.

Dynamic HTML (DHTML)

DHTML is not a new language. It is a way to make HTML pages change without reloading. Example: Dropdown menus, Live updates on a page.

Components of DHTML

DOM (Document Object Model), Scripts (JavaScript), CSS, XHTML.

DOM (Document Object Model)

DOM is what allows a web page to be accessed and changed dynamically. It represents every part of a web page (text, images, buttons, forms) as objects. DOM gives standard names to page elements so scripts can find and modify them.

Why DOM is important: It makes DHTML possible. You can: Change text, Change colors, Hide or show elements, Move objects on the page.

> 📌 **Example:**
>
> Changing a button color when the user clicks it.

Scripts

Scripts are used to control DOM objects. Most common scripting languages in DHTML: JavaScript, ActiveX (older, mostly Internet Explorer).

📌 Scripts decide what happens when a user clicks, types, or moves the mouse.

CSS in DHTML (Cascading Style Sheets)

CSS controls how the page looks. It defines: Colors, Fonts, Backgrounds, Position of elements. With DOM + Scripts: CSS styles can be changed dynamically.

> 📌 **Example:**
>
> Text turns red when you hover the mouse over it.

XHTML in DHTML

DHTML pages are written using HTML 4.x or XHTML. DHTML is not a new language. It uses: HTML/XHTML → structure, CSS → appearance, DOM + Scripts → behavior.

Four Features of DHTML

1. **Changing Tags and Properties:** DHTML can change HTML elements based on events. Content can be loaded but hidden until needed. 📌 Example: Hidden help text appears when the user clicks “Help”.
2. **Real-Time Positioning:** Objects (text, images) can move on the page. Often used in: Games, Animations, Interactive dashboards.
3. **Dynamic Fonts:** Fonts are downloaded with the page. Ensures the page looks the same on all systems. Originally a Netscape-only feature.
4. **Data Binding:** Internet Explorer–only feature. Allows web pages to connect directly to databases. Uses ActiveX controls. Similar to CGI, but easier for Microsoft systems.

JavaScript

JavaScript adds functionality and interaction to HTML. It runs on the user’s browser, not the server. This makes it fast and responsive.

Common Uses of JavaScript: Opening popup windows, Validating form inputs, Changing images on mouse hover, Detecting key presses.

> 📌 **Example:**
>
> Checking if a password field is empty before submitting a form.

JavaScript Key Points: Client-side scripting language, Looks like Java but is not Java, Uses C-style syntax, Designed to be easy for non-programmers, Can detect user actions that HTML cannot. 📌 Browsers expose the DOM to JavaScript using host objects.

Sample JavaScript Code (Simple)

```
<script type="text/javascript">
document.write('Hello World!');
</script>
```

Writes “Hello World!” on the webpage. `<noscript>` shows a message if JavaScript is disabled.

INFRASTRUCTURE AND VIRTUALIZATION

Infrastructure

Infrastructure delivers virtualization for cloud computing. Virtualization can be local or over the Internet.

Virtualization

Virtualization allows: One physical machine To run multiple virtual machines. Many companies collaborated to create open standards: VMware, Intel, IBM, Dell, Red Hat, etc.

VMware Community Source

VMware opened access to ESX Server APIs. Partners can: Improve virtualization, Build compatible solutions. Benefits: More virtualization solutions, Better interoperability, Faster development of cloud-aware technologies.

Open Hypervisor Standards

Hypervisor = software that runs virtual machines. Open standards help: Avoid vendor lock-in, Enable VM migration, Improve compatibility. Focus Areas: Cross-platform VM management, APIs between hypervisors and guest OS, Standard VM formats.

Community Source Program

Partners get access to VMware ESX source code. Encourages: Collaboration, Innovation, Interoperability. 📌 Benefit to customers: More compatible and better-integrated virtualization solutions.

OVF (Open Virtualization Format)

OVF is a vendor-neutral format for virtual machines. Allows virtual appliances to run on any hypervisor.

Key Features: Platform independent, Prevents vendor lock-in, Portable VM packaging, Supports integrity checking and licensing, Easy installation and validation. 📌 OVF makes moving VMs between platforms simple.

Web Services

A web service allows machine-to-machine communication. Defined by W3C. Uses: HTTP, XML, APIs.

Data Formats: JSON and XML

JSON (JavaScript Object Notation)

Lightweight data format, Easy to read and write, Ideal for JavaScript and AJAX, Faster and less overhead than XML.

```
📌 Example:
{
"firstName": "Johnny",
"lastName": "Johnson",
"phoneNumbers": ["612555-9871", "952555-1598"]
}
```

XML (Extensible Markup Language)

Self-describing data format, Platform independent, Separates content from presentation, Used widely in cloud systems.

XML Advantages: No schema required, Supports complex and rich data, Works well with databases, Easy to extend, Industry standard (W3C approved).

XML vs JSON (Very Important)

Feature	JSON	XML
Speed	Faster	Slower
JavaScript use	Excellent	Complex
Overhead	Low	High
Parsing	Easy	Needs DOM processing

📌 **Rule:** Use JSON when JavaScript is involved.

REST (Representational State Transfer)

REST is an architectural style. Uses: HTTP, URLs, XML or JSON.

How REST Works: Data is exposed at a URL, Client reads and displays it.

> 📌 **Example:**
>
> Fetching weather data from a cloud API using a URL.

Benefits of REST: Faster response, Lower server load, Scales easily, Works with browsers, Bookmarkable URLs, Easy sharing via email or chat, Backward compatible.

SOAP (Simple Object Access Protocol)

SOAP allows programs on different systems to communicate. Uses: HTTP, XML.

Why SOAP? Firewalls allow HTTP, SOAP messages pass easily, Supports complex program interactions. 📌 SOAP is more powerful but more complex than REST.
